

Properties of Common Minerals

Figures from Winter's web page (2002)

Groups Considered

- Framework silicates
- Sheet silicates
- Pyroxenes
- Amphiboles
- Other Silicates
- Non Silicates

Framework Silicates

- Feldspars
- Feldspathoids
- Silica polymorphs

Feldspars

- Simple chemistry
- Substitution of Na for K or NaAl for CaAl
- Crystal systems
 - Monoclinic (orthoclase, sanidine)
 - Triclinic (plagioclase, microcline)
- Tabular habit

Feldspar Twinning

- Simple twins (two parts)
 - Carlsbad
 - Common in monoclinic feldspars
- Polysynthetic twins
 - Albite and others
 - Common in triclinic feldspars

K-spars

- Orthoclase, Sanidine, Microcline
- All optically negative
- All have $n \sim 1.53$
- Distinguished by $2V$
 - Sanidine $2V = 0-30^\circ$
 - Orthoclase $2V = 30-70^\circ$
 - Microcline $2V = 70-90^\circ$
- Microcline has Scotch plaid twins

Plagioclase

- Refractive index increases with Ca content
 - Varies between 1.53 (Ab) to 1.57 (An)
- 2V is large and varies with composition
- Optic sign depends on composition (+/-)

Common Sheet Silicates

- Muscovite
- Phlogopite
- Biotite
- Chlorite

Sheet Structures

Classified on the basis of Si-O polymerism

$[\text{Si}_2\text{O}_5]^{2-}$ Sheets of tetrahedra
micas talc clay minerals serpentine

Phyllosilicates

SiO_4 tetrahedra polymerized into 2-D sheets: $[\text{Si}_2\text{O}_5]$
Apical O's are unpolymerized and are bonded to other constituents

Building Blocks

- Tetrahedral layers
- Octahedral layers
- Large Cation layers
- Weak bonds along (001)

Common Sheet Properties

- Crystals are platy parallel to (001)
- Perfect cleavage follows (001)
- 2V is small (0-40°)
- Extinction is parallel to (001)
- BxA perpendicular to (001)
- Optic sign can be determined by 1st order plate

Brucite: $Mg(OH)_2$

Octahedral layers can be understood by analogy with hydroxides

Layers of octahedral Mg in coordination with (OH)

Large spacing along c due to weak van der Waals bonds

Gibbsite $Al(OH)_3$

- Layers of octahedral Al in coordination with (OH)
- Al^{3+} means that only 2/3 of the VI sites may be occupied for charge-balance
- Brucite-type layers may be called trioctahedral and gibbsite-type dioctahedral

Kaolinite: $Al_2 [Si_2O_5] (OH)_4$

T-layers and dioctahedral (Al^{3+}) layers
(OH) at center of T-rings and fill base of VI layer →

weak van der Waals bonds between T-O groups

O

Mica Properties

- All micas are optically negative
- $2V$ is small ($0-40^\circ$)
- (001) sheets give BxA figures
- Birefringence is large (0.035-0.045)
- “Birds eye” effect is obvious due to bent cleavages

Chlorite

- $(Mg, Fe)_3 [(Si, Al)_4O_{10}] (OH)_2 (Mg, Fe)_3 (OH)_6$
- T - O - T - (brucite) - T - O - T - (brucite) - T - O - T
- Very hydrated $(OH)_8$
- Low-temperature stability
- Low-T metamorphism and alteration product of mafics

Chlorite Optics

- $2V$ is small (0-20°)
- Birefringence is low (0.001-0.010)
- Some optically positive, some negative
- Extinction parallel to (001)
- Some types have strong dispersion
- Some types weakly pleochroic

Other Sheet Silicates

- Talc
 - Pale green, high birefringence
- Stilpnomelane
 - Pleochroic (yellow to brown or green)
- Chloritoid
 - Hour glass inclusions, polysynthetic twins, cross fractures, inclined extinction

Mineral Structures

Silicates are classified on the basis of Si-O polymerism

$[\text{SiO}_3]_n^{2-}$ single chains
pyroxenes pyroxenoids

Inosilicates $[\text{Si}_4\text{O}_{11}]_n^{4-}$ Double tetrahedra
amphiboles

Amphiboles

- Two cleavages at 120°
- Crystals elongate parallel to c
- Extinction Z^c small (10-20°)
- Color and pleochroism generally strong
- Optic sign negative
- $2V$ is large (70-90°)

Amphibole Groups

- Non calcic amphiboles
 - Anthophyllite (orthorhombic)
 - Cummingtonite (monoclinic)
- Calcic amphiboles
 - Tremolite-actinolite
 - Hornblende-oxyhornblende
- Sodic amphiboles
 - Glaucophan, Riebeckite, Arfvedsonite

Amphibole Chemistry

See handout for more information

General formula:

W = Na K

X = Ca Na Mg Fe²⁺ (Mn Li)

Y = Mg Fe²⁺ Mn Al Fe³⁺ Ti

Z = Si Al

Again, the great variety of sites and sizes → a great chemical range, and hence a broad stability range

The **hydrous** nature implies an upper temperature stability limit

Amphibole Chemistry

Ca-Mg-Fe Amphibole “quadrilateral” (good analogy with pyroxenes)

Al and Na tend to stabilize the orthorhombic form in low-Ca amphiboles, so anthophyllite ↔ gedrite orthorhombic series extends to Fe-rich gedrite in more Na-Al-rich compositions

Hornblende

- Strongly pleochroic
- $Z^c = 20^\circ$
- Birefringence = 0.020
- $2V_x = 70^\circ$
- Can be named green or brown hornblende
- Reddish varieties are oxyhornblende and kaersutite (Ti-rich hornblende)

Amphibole Chemistry

Hornblende has Al in the tetrahedral site

Geologists traditionally use the term “hornblende” as a catch-all term for practically any dark amphibole. Now the common use of the microprobe has petrologists casting “hornblende” into end-member compositions and naming amphiboles after a well-represented end-member.

Sodic amphiboles

Glaucofan: $\text{Na}_2\text{Mg}_3\text{Al}_2[\text{Si}_4\text{O}_{22}](\text{OH})_2$

Riebeckite: $\text{Na}_2\text{Fe}^{2+}_3\text{Fe}^{3+}_2[\text{Si}_4\text{O}_{22}](\text{OH})_2$

Sodic amphiboles are commonly blue, and often called “blue amphiboles”

General Pyroxene Characteristics

- Two cleavages at 87°
- Stumpy crystals
- Z^c large for monoclinic minerals
- Colorless or weakly pleochroic
- Optic sign positive
- $2V$ is moderate ($40-60^\circ$)

Single Chains- Pyroxenes

Diopside (001) view blue = Si purple = M1 (Mg) yellow = M2 (Ca)

Pyroxene Chemistry

The general pyroxene formula:

Where

- W = Ca Na
- X = Mg Fe^{2+} Mn Ni Li
- Y = Al Fe^{3+} Cr Ti
- Z = Si Al

Anhydrous so high-temperature or dry conditions favor pyroxenes over amphiboles

Pyroxene Chemistry

The pyroxene quadrilateral and opx-cpx solvus

Coexisting opx + cpx in many rocks (pigeonite only in volcanics)

Enstatite and Hypersthene

- Non-calcic Pyroxenes
- Enstatite
 - $2V_z = 60-90^\circ$
 - Birefringence = 0.008
- Hypersthene
 - $2V_x = 50-90^\circ$
 - Birefringence – 0.014
 - Weakly pleochroic pink to pale green

Diopside and Augite

- Colorless
- Birefringence of 0.020-0.030
- $2V_z = 60^\circ$
- $Z^c = 40^\circ$
- Pigeonite has $2V_z = 0-30^\circ$

Sodic Pyroxenes

- Aegerine ($\text{NaFeSi}_2\text{O}_6$)
 - Strongly pleochroic in green
 - $X^c = 2-6^\circ$
 - High birefringence (~0.050)
- Jadeite ($\text{NaAlSi}_2\text{O}_6$)
 - Moderate birefringence (~0.020)
 - $Z^c = 30^\circ$

Independent SiO_4 Tetrahedra

- Olivine Occurrences:
 - Principally in mafic and ultramafic igneous and meta-igneous rocks
 - Fayalite in meta-ironstones and in some alkalic granitoids
 - Forsterite in some siliceous dolomitic marbles
- Monticellite CaMgSiO_4
 - $\text{Ca} \rightarrow \text{M2}$ (larger ion, larger site)
 - High grade metamorphic siliceous carbonates
